Abstract

Introduction: Insulin resistance, obesity and inflammation are hallmark features of type 2 diabetes and metabolic syndrome. Type 2 diabetes is a major risk factor for developing atherosclerotic vascular disease. The cluster of all these risk factors is being termed as cardiometabolic risks. New tools must be made available to patients and their physicians to formulate optimal treatment strategies for effective management of such cardiometabolic risk conditions. The goal of this study is to develop a minimally invasive dried blood assay to screen and monitor patients at risk of developing cardiovascular and metabolic complications.

Methods: Blood spots obtained from finger sticks on a filter paper were air-dried for 4 hours at room temperature after collection from volunteers. Using an automated dried blood spot (DBS) puncher, 6.0 mm bloodspot disks were obtained and rehydrated in assay buffer/ methanol for further testing. New modified methods were developed from commercially available assays to test insulin, hs-C-reactive protein, triglycerides and HbA1c.

Results: Blood spot and serum insulin levels correlated well in fasting (R = 0.99) and non-fasting (R = 0.93) samples. A positive correlation was observed for hs-CRP (R = 0.98) and triglycerides (R = 0.93) between bloodspot and serum values. HbA1c levels tested in blood spots (5.41 ± 1.06%) were comparable to the whole blood values (5.44 ± 1.08%). Assay range 3.36-12.02% were comparable to the whole blood values. The intra and inter-assay variations in all these assays ranged between 4.39-14.39% respectively.

Conclusion: Our results suggest that the new improved, minimally invasive assay in dried blood provides reliable and convenient tool for better management and control of patients with cardiometabolic risk conditions. These assays are a fully automated, sensitive, specific and have high throughput potential.

Background

Cardiometabolic Health Monitoring using Dried Blood Spot

Methods

Bloodspot Insulin
Fasting and non-fasting healthy subjects contributed a blood spot sample from a finger-stick and a blood sample through venipuncture for serum isolation. The blood spots obtained from finger sticks were air-dried at room temperature after collection and stored at -20°C within 24 hr of collection. Serum was stored frozen at -20°C. Standards and controls for blood spots were prepared by mixing washed red blood cells 55/45 with insulin kit standards and controls and drying on blood spot filter paper. Serum and rehydrated blood spots were tested in parallel for insulin using the commercial ELISA kits from DRG.

Bloodspot hs-CRP
Serum and dried blood spot samples from volunteers were collected and stored as explained above. One 6.0 mm disk of dried bloodspot was punched and 200 µL of extraction buffer was added and incubated at room temperature for two hours. A 20 µL of extracted sample and 100 µL of CRP enzyme conjugate was added and incubated at room temperature for 45 minutes in a 96 well plate. After washing with distilled water 100 µL of substrate TMB solution was added and incubated for 20 minutes. The reaction was stopped by adding 100 µL of stop solution and the plate was read at 450 nm with 620 nm.

Bloodspot Triglycerides
Bloodspot extract was prepared by punching out two 6.0 mm disks from bloodspots and 200 µL of methanol was added to each well. The plate was then incubated for 2 hours at 37°C. Triglycerides were measured by modifying the method of Qurashi et al. with 50 µL of sample, standards, controls or blanks were added to 250 µL of triglyceride reagent (Random) and incubated at 37°C for 10 minutes. The absorbance was read using the Wells-Matar 1420 Multiblend Counter set to 490 nm. Serum triglyceride levels were determined using the same assay kit.

Hemoglobin A1c
The method is based on the interaction between antigen and antibody to directly determine the HbA1c in extracted blood from paper disks. HbA1c in blood is known to bind to latex particles. Therefore, a latex-HbA1c/mouse anti-human HbA1c antibody complex is formed when mouse anti-human HbA1c monoclonal antibody is added. Further, addition of goat anti-mouse IgG polyclonal antibody forms an agglutination by interacting with the monoclonal antibody. The concentration of HbA1c is proportional to the total amount of agglutination. The amount of agglutination is measured as absorbance. The HbA1c value is obtained from a calibration curve. One large spot was punched using the multipuncher and 500 µL of lysis buffer was added. The extraction plate was incubated for 2 hours at RT. Twenty microliters of this lysate was added and incubated at 37 C followed by addition of 60 µL goat anti-mouse IgG polyclonal antibody. Microplate reader was incubated at 37°C for five minutes and read at 450 nm ± 15 nm.

Results

Bloodspot Collection

Cardiovascular and metabolic factors are gaining attention as potential targets of intervention in the prevention and treatment of cardiovascular disease and type 2 diabetes mellitus. New tools will enable clinicians formulate treatment strategies for the prevention and management of cardiovascular and metabolic conditions. In this study, we present an improved high throughput screening method for estimation of insulin, high sensitivity (hs)-C-reactive protein and hemoglobin A1c in dried blood spot. As insulin resistance and CRP levels have been associated with cardiometabolic risk, measurement of CRP levels along with insulin may help in the assessment of potential cardiovascular risk. The role of triglycerides as risk factor in cardiovascular and coronary artery disease has been studied by several investigators. ADA has suggested that HbA1c is a better screening tool for diabetes and prediabetes than oral glucose. This blood spot methods have been used by several investigators because of the low cost, ease of sample collection and transport. In addition, patients and clinicians prefer these methods due to small sample requirements and minimal invasiveness as compared to venipuncture. A few of the studies have earlier reported laboratory protocols for insulin, c-reactive protein and triglycerides in dried blood spot. The dried blood assays in our laboratory have shown improvements in terms of precision, accuracy and ease of high throughput screening of these biomarkers.

Discussion

The stability, efficient recovery, and excellent correlation between levels of these markers in dried blood spot and serum makes these available and convenient tool for screening of cardiometabolic risk factors. A bloodspot panel consisting of fasting insulin, hs-CRP, HbA1c and triglycerides along with blood pressure and cholesterol level assessments is recommended for a population at risk and also for those with diagnosed cardiovascular disease or type 2 diabetes mellitus.
