An Epidemic

In 2010 the US was ranked as the world’s fattest developed nation, and the latest data out of the CDC reports over a third of American adults obese—with the highest prevalence among men and women over 40 years old. It is not a coincidence that this is the age when people start to see the impacts of hormonal imbalance. Providers can help by addressing the hormonal connection to obesity to help patients manage their weight and reduce related disease risks.

ZRT’s Weight Management Profile

The Weight Management Profile identifies hormonal imbalances that contribute to obesity, weight gain and difficulty losing or sustaining a healthy weight. Used as a screening tool, the profile also serves as a powerful early indicator of insulin resistance and risks for metabolic syndrome and diabetes.

Purpose

- Identify hormonal imbalances associated with weight gain and obesity
- Detect risk markers for insulin resistance, metabolic syndrome and diabetes

What is Included in the Profile?

**Weight Management Profile**

- Estradiol (E2)
- Progesterone (Pg)
- Testosterone (T)
- DHEA-S (DS)
- Diurnal Cortisol (Cx4)
- Thyroid Stimulating Hormone (TSH)
- Vitamin D (D2, D3)
- Insulin (In)
- Hemoglobin A1c (HbA1c)

*OPTIONAL profiles available at a discounted price when ordered with Weight Management Profile.

*OPTIONAL THYROID

- Free Triiodothyronine (fT3)
- Free Thyroxine (fT4)
- Thyroid Peroxidase Antibodies (TPO)

Add on: when symptoms of thyroid deficiency are problematic

Advantage: better estimation of thyroid hormone bioavailability to facilitate effective thyroid therapy

*OPTIONAL CARDIO

- High Sensitivity C-Reactive Protein (hsCRP)
- Triglycerides (TG)
- Total Cholesterol (CH)
- LDL Cholesterol (LDL)
- VLDL Cholesterol (VLDL)
- HDL Cholesterol (HDL)

Add on: with abdominal obesity, and symptoms of insulin resistance/metabolic syndrome

Advantage: early detection of pro-inflammatory CVD risks, metabolic syndrome, and pre-diabetes
excessive supplementation with progesterone to higher than normal levels can increase appetite and also slow the rate of food emptying from the stomach and moving through the digestive tract, causing slower digestion and bloating.

**Testosterone (T) and DHEA-S (DS)** are androgens that increase lean muscle mass and metabolic rate. As androgen levels decline, muscle mass also decreases with a corresponding increase in adiposity. Low androgens can also reduce vitality and tolerance for exercise. Weight gain itself, with its resulting hormone imbalances, can trigger a drop in testosterone as the aromatase enzyme within fat tissue converts androgens to estrogens. In men this contributes to a female-type body fat distribution, including breast tissue development. In women with polycystic ovarian syndrome (PCOS), high testosterone and DHEA are linked to insulin resistance and weight gain, particularly in the abdomen.

**Cortisol (C)** imbalances can create problems with blood sugar control, sleep patterns, appetite, food cravings, and tolerance for exercise. Under stress, excessive cortisol production particularly in concert with insulin, promotes fat storage in abdominal adipose tissue. This visceral type of fat is closely associated with insulin resistance and metabolic syndrome and thus more hazardous to health. Chronically elevated cortisol is a known risk factor for pre-diabetes and cardiovascular disease.

**Thyroid Stimulating Hormone (TSH)** elevations, even within the high-normal range, are linked with hypothyroidism, low metabolic rate and obesity. Hypothyroidism is linked to elevated cortisol and can also be a consequence of oral estrogen therapy, which increases the production of binding proteins that reduce thyroid hormone bioavailability.

**Vitamin D (D2, D3)** deficiency is common in obesity and particularly associated with hyperinsulinemia and visceral fat. Whether by cause or effect, identifying and correcting vitamin D3 deficiency may improve insulin sensitivity.

**Fasting Insulin** (In), when elevated, is a marker of insulin resistance which precedes metabolic syndrome, PCOS, and type 2 diabetes. Increased levels, particularly in concert with cortisol lead to central obesity and increased inflammatory and other cardiovascular disease markers. Hyperinsulinemia also contributes to decreased testosterone levels in men, but increased testosterone and decreased ovulation in women.

**Hemoglobin A1c** (HbA1c) is an indirect measure of the average circulating glucose levels over the previous three months. An HbA1c of more than 6% is predictive of type 2 diabetes and cardiovascular disease risk.

**Hormone Weight Gain Connection**

**Estrogen/progesterone imbalance**: weight gain in hips, thighs; water retention; low thyroid/metabolism

**Testosterone/DHEA imbalance**: decreased lean muscle, low metabolic rate; abdominal obesity

**Cortisol imbalance**: increased appetite, sugar cravings, and belly fat; inhibits thyroid and metabolism

**Vitamin D3 deficiency**: hyperinsulinemia; visceral fat

**TSH elevated**: hypothyroidism, low metabolic rate, obesity

**Fasting Insulin**: insulin resistance, abdominal obesity

**HbA1c**: predictive of type 2 diabetes
Clinical Utility
The Weight Management Profile allows providers to identify specific hormone imbalances associated with excess weight gain or obesity, vitamin D deficiency, and hypothyroidism in their patients. As a risk assessment panel it allows for early detection of insulin resistance, metabolic syndrome, and type 2 diabetes. The comprehensive test report is designed to help clinicians recommend effective treatments to rebalance hormone levels, address vitamin D and thyroid deficiencies, reduce overall risk for metabolic syndrome, and potentially avoid the onset of type 2 diabetes.

Who Benefits from Profile Testing?
Menopausal women/andropausal men with unexplained weight gain, obesity, abdominal fat, high BMI (body mass index), hypometabolism. Commonly related symptoms include loss of lean muscle, increased appetite and/or sugar cravings, chronic stress, and low thyroid symptoms.

Advantages of Saliva and Blood Spot Testing
• Convenient sample collection at home - no phlebotomist required
• Easy shipment of samples from home to the lab
• Samples stable for several weeks at room temperature
• Excellent correlation with serum/plasma assays
